Alginates Biology and Applications in Microbiology

Alginates, also known as alginates or alginic acid salts, are naturally occurring polysaccharides derived primarily from brown seaweeds (Phaeophyceae). Their unique chemical structure, biocompatibility, and gel-forming capabilities have positioned them as critical biomaterials across various scientific disciplines, notably microbiology. This review aims to explore the biology of alginates, their molecular structure, biosynthesis, and the myriad of applications they have found in microbiology, including antimicrobial strategies, biofilm research, and biotechnological innovations.

Understanding Alginates: Structural and Biological Foundations

Chemical Structure of Alginates

Alginates are linear copolymers composed primarily of two uronic acid monomers: α -D-mannuronic acid (M) and α -L-guluronic acid (G). These monomers are linked via 1 $\rightarrow$ 4 glycosidic bonds, creating an alternating or block arrangement that imparts distinctive physical properties.

Key features include:

- Block Composition: Alginates consist of homopolymeric blocks of M (poly-M), G (poly-G), and heteropolymeric blocks (M-G).

- Gelling Properties: The presence of G-blocks facilitates ionic crosslinking with divalent cations like calcium, forming gels with applications in encapsulation and tissue engineering.
- Molecular Weight: Typically ranges from 32,000 to over 400,000 Da, influencing viscosity and gel strength.

Biological Origin and Biosynthesis

Alginates are predominantly extracted from brown seaweeds such as Laminaria, Macrocystis, and Ascophyllum. These macroalgae synthesize alginate as a structural component of their cell walls, contributing to mechanical stability and flexibility.

In microbial systems, certain bacteria, notably Pseudomonas and Azotobacter species, produce alginate as an exopolysaccharide (EPS). This bacterial alginate plays essential roles in biofilm formation, protection against environmental stresses, and pathogenicity.

The biosynthesis pathway involves:

- Precursor Formation: UDP-glucose is converted into UDP-mannuronic acid.
- Polymerization: Enzymes called alginate synthases assemble the copolymer on the inner membrane.
- Modification: Deacetylases and epimerases modify the polymer, affecting physical properties.
